

# CRP 4080: Introduction to Geographic Information Systems for planners

## Lecture 4: Geoprocessing

Wenzheng Li, Ph.D.  
City and Regional Planning  
Fall 2024

# Milestone

## Intro: Getting to Know ArcGIS Pro and Basic Mapping

- What is GIS
- Operating ArcGIS Pro
- Thematic Mapping
- Map Projection

- Now...Geo-spatial data management

# Final project

Proposals (1-2 paragraphs)

- Due: October 10 (submit via Canvas)
- Project idea (research question)
- Possible data sources (with website links if possible)

Project idea must require use of GIS (ie have some sort of spatial component)

- ✚ Analytical, not just descriptive: Use GIS to answer a question e.g. suitability study
- ✚ Exit (capstone) projects, client-based projects

Final Project examples will be posted on Thursday...

# Recap

## What is Spatial Analysis in GIS?

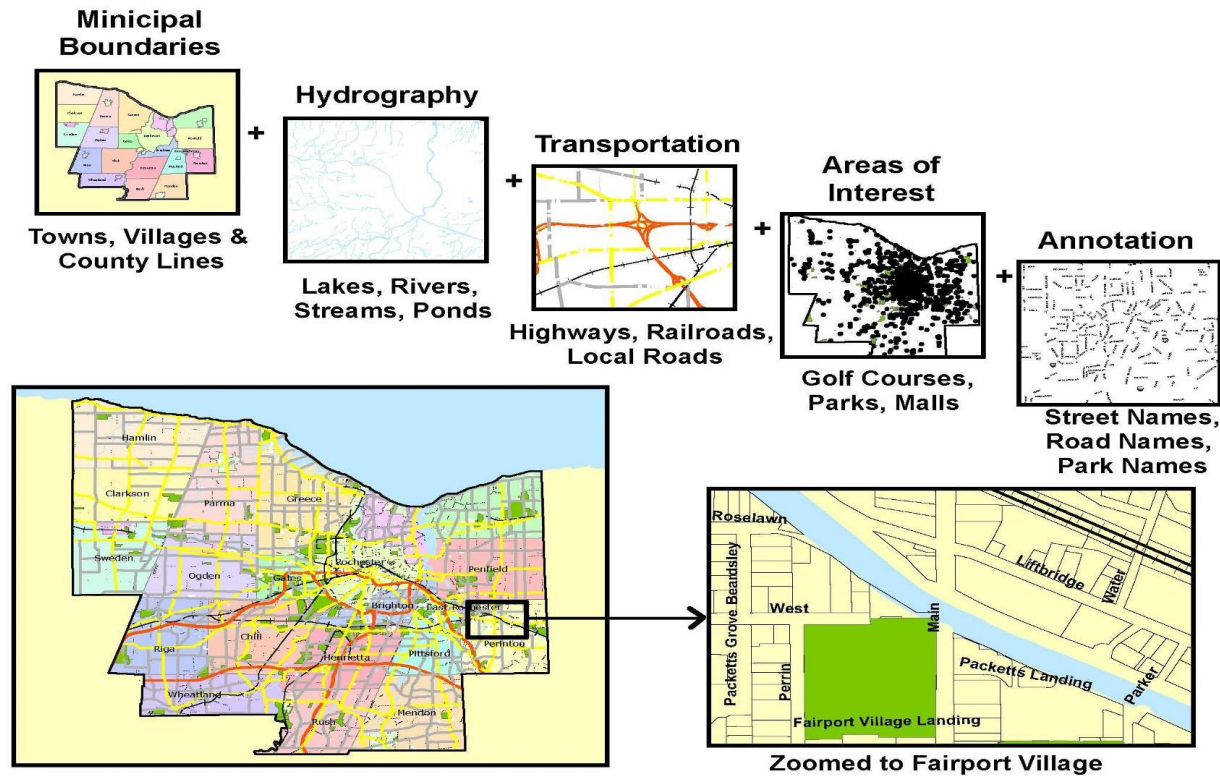

Image source

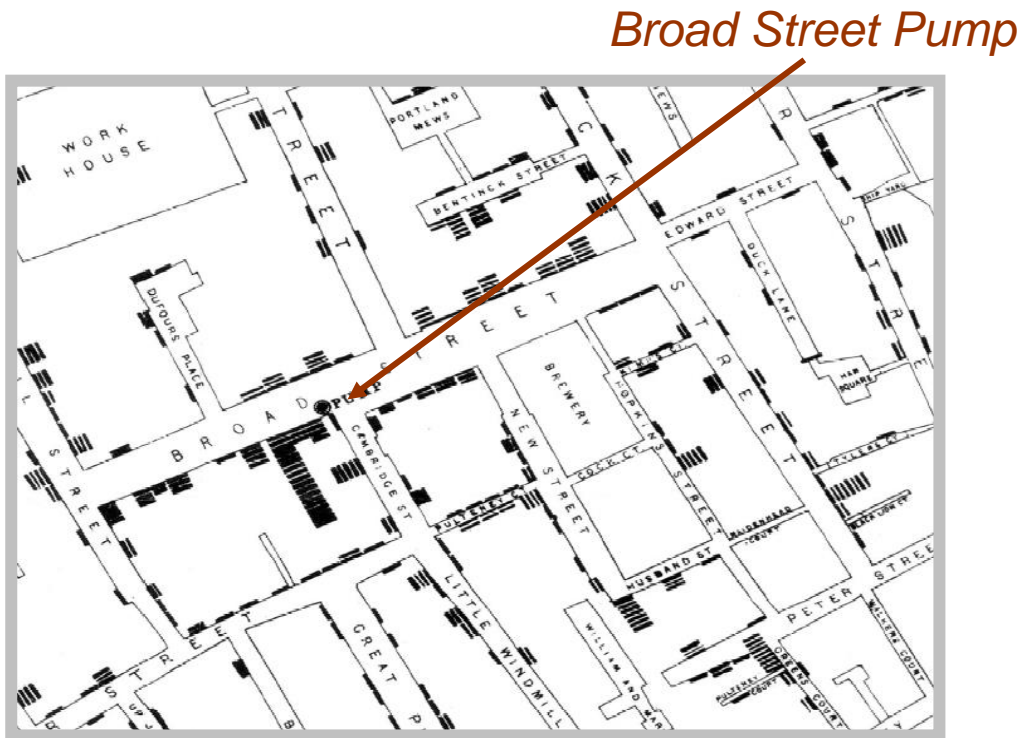

- First step: **Overlay** spatial features/data to tell a story, make an argument, solve or understand a problem, etc about **locations**.
- Second step: Share your spatial analysis in reports, maps, tables, and charts through visual communication.

# Spatial Analysis

- “...to examine relationships between geographic features collectively and to use the relationships to describe the real-world phenomena that map features represent.” (Clarke 2001, 182).
- A method of analysis is spatial if the results depend on the locations of the objects being analyzed
  - move the objects and the results change
- Spatial analysis requires both attributes and locations of objects
  - Spatial info to plot on map (e.g., lng/lat)
  - and the non-spatial data attributes (e.g., population, income, forests, animal habitats, etc.

# Spatial Analysis in GIS

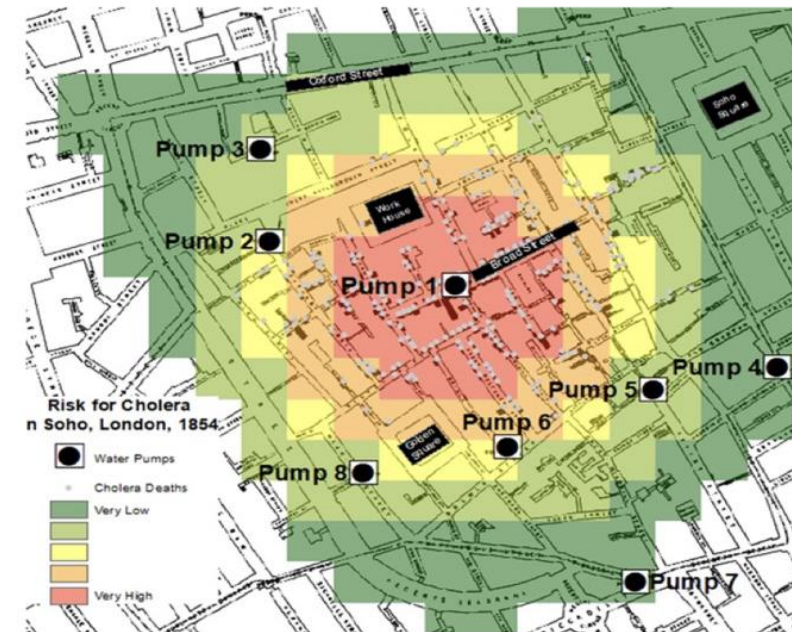

- The Snow Map of Cholera Incidence in the area of Broad Street, London, in 1854. The contaminated water pumps is located at the center of the map.

water pump-wells (●)

deaths from cholera (|||||)

**Risk Terrain Map of Model 2: High-risk places for cholera victimization in Soho, London, 1854.**

Source: Caplan JM, Kennedy LW, Neudecker CH (2020) Cholera deaths in Soho, London, 1854: Risk Terrain Modeling for epidemiological investigations. PLOS ONE 15(3): e0230725.  
<https://doi.org/10.1371/journal.pone.0230725>

## Spatial analysis can be:

- **inductive**, to examine empirical evidence in the search for patterns that might support new theories or general principles.
- Four steps: **Observations, pattern discovery, analytics, and conclusion.**
  - e.g., the disease map
  - e.g., crime rates are higher in certain areas of a city

# Spatial analysis can be – inductive

Why Some Immigrant Neighborhoods Are Safer than Others

FIGURE 1  
Violent Crime and Immigrant Neighborhoods: Chicago

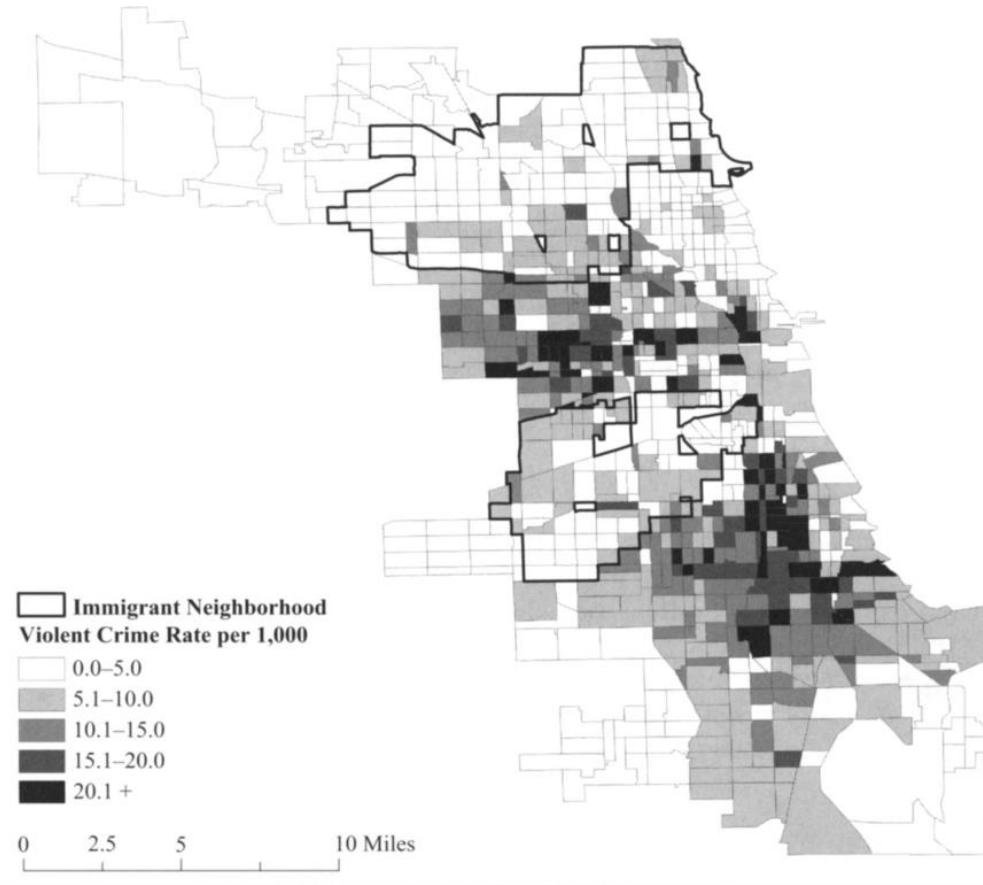

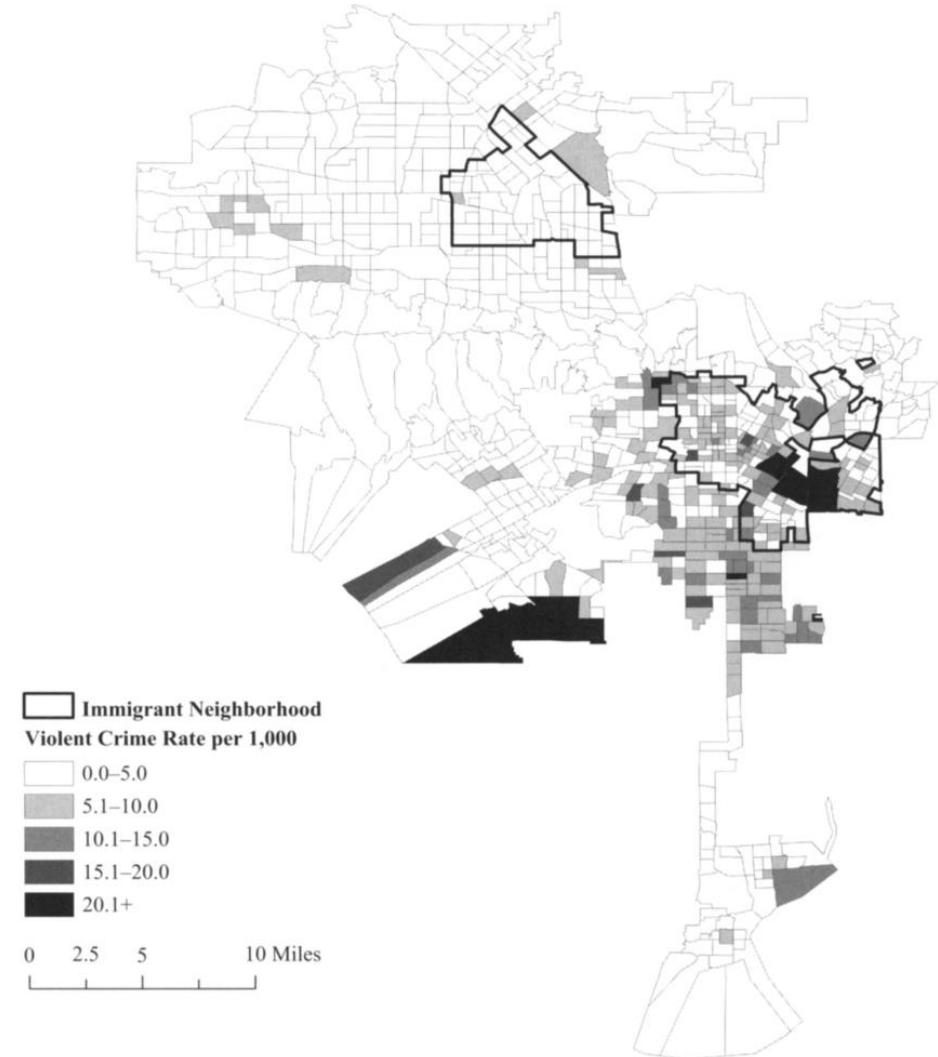

FIGURE 2  
Violent Crime and Immigrant Neighborhoods: Los Angeles

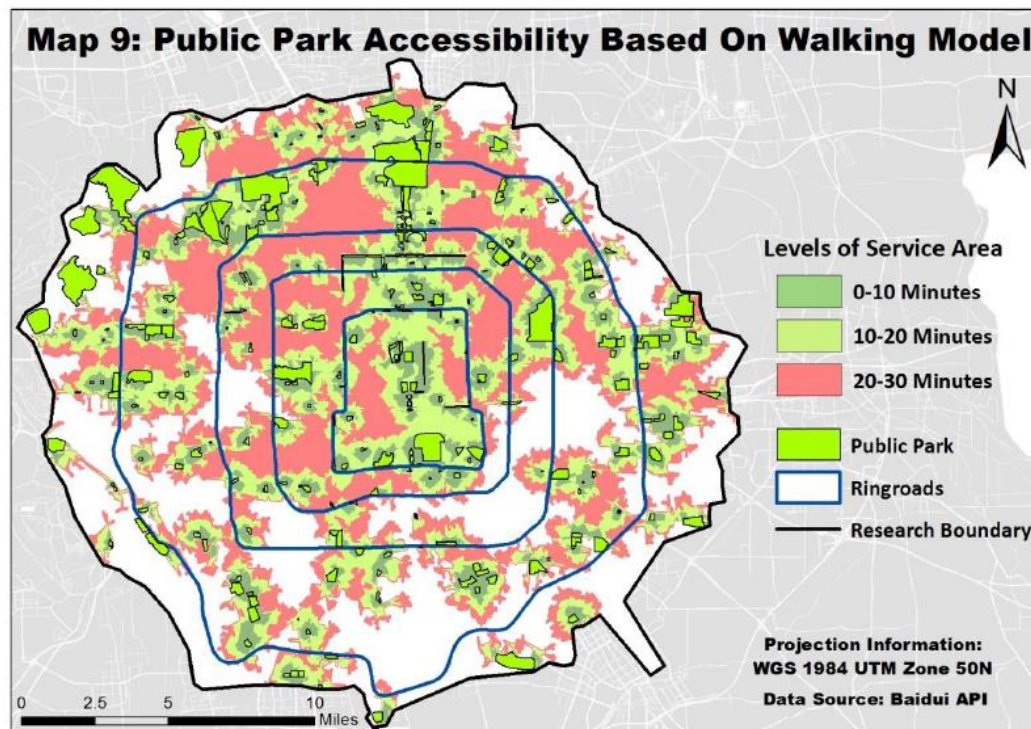

# Spatial analysis can be:

- **deductive**, focusing on the testing of known theories or principles against data – starts with a hypothesis or theory, and then looks for evidence in the spatial data to support or refute it.

e.g., **Hypothesis** - Higher level of urban green spaces accessibility leads to higher property prices.

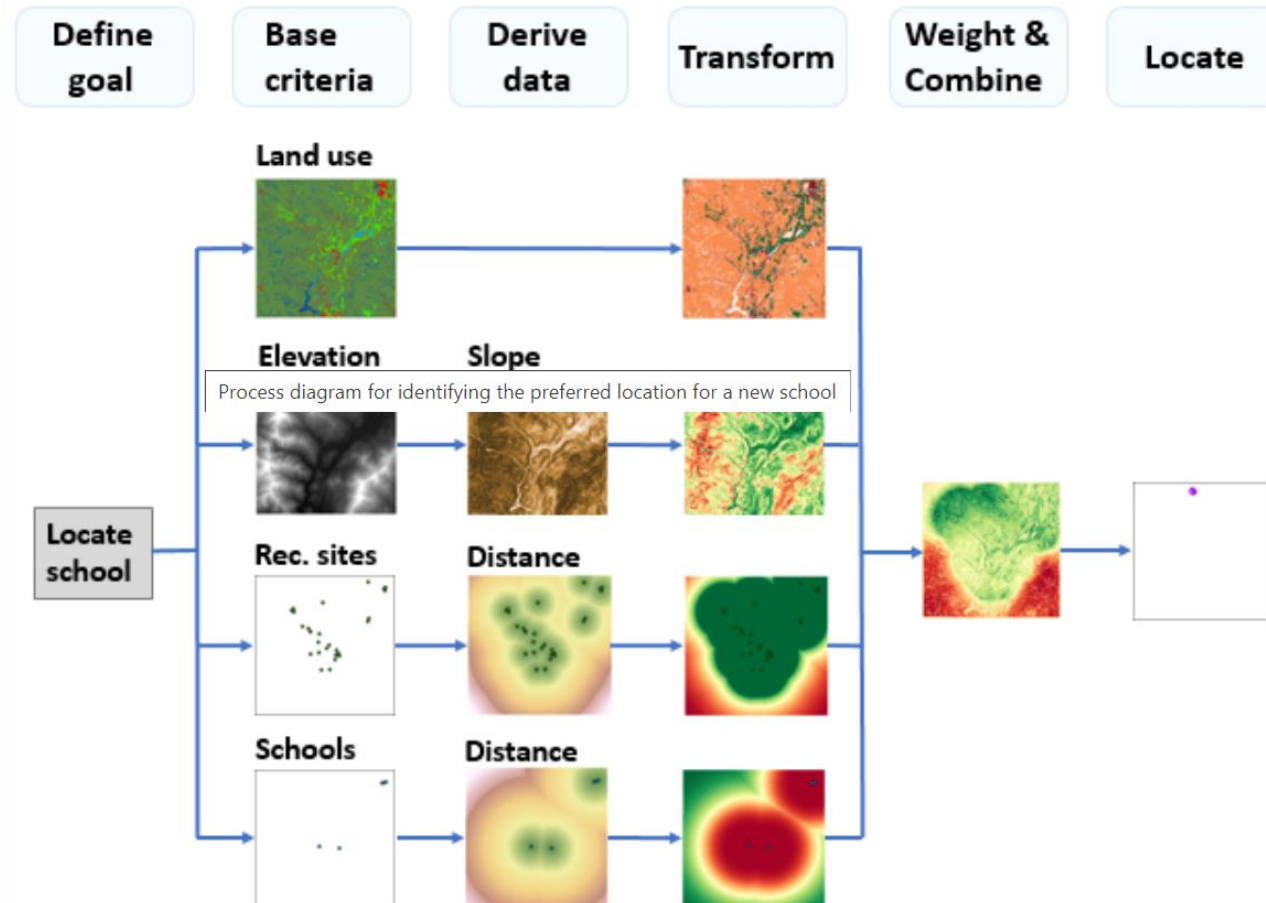

Public park accessibility in Beijing (Walking model)

The relationship between public park accessibility and housing price

# Spatial analysis can be:

- **normative**, using spatial analysis to develop or prescribe new or better designs, patterns, etc.

Process diagram for identifying the preferred location for a new school.

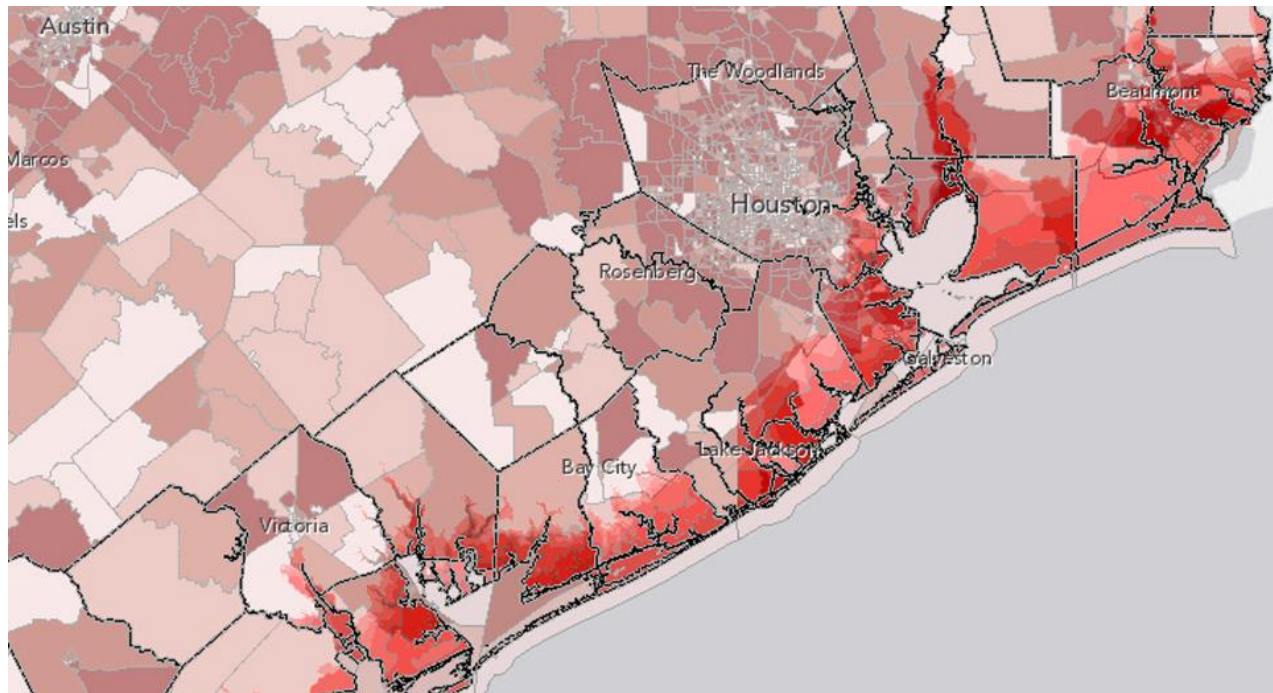

## Public service Planning

Land use suitability analysis

- e.g., Where should we locate an elementary school?
- Location-allocation modeling – know your demand (population?)
- Zoning/land use (permission to build?)
- Elevation (relatively flat)?
- Close to a recreation site

# Spatial analysis can be - normative

## Hazard Mitigation

<http://pubs.usgs.gov/fs/2011/3008/>

Example from Texas Sustainable and Resilient Planning Atlases: Mapping the environmental hazards

- Where are these hazards?
- Which neighborhoods face the most hazard risks?
- Where are mitigation mostly needed
- Where should future growth occur

Image source

# Geoprocessing

- Geoprocessing is the manipulation of geographic data.
- It provides a way to create new information by applying an operation to existing data.
- A typical geoprocessing operation takes an input dataset, performs an operation on that dataset, and returns the result of the operation as an output dataset or derived data

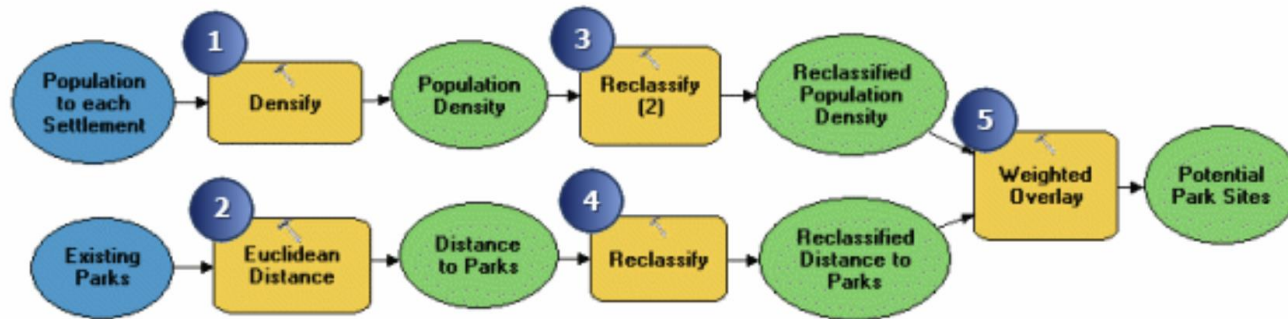

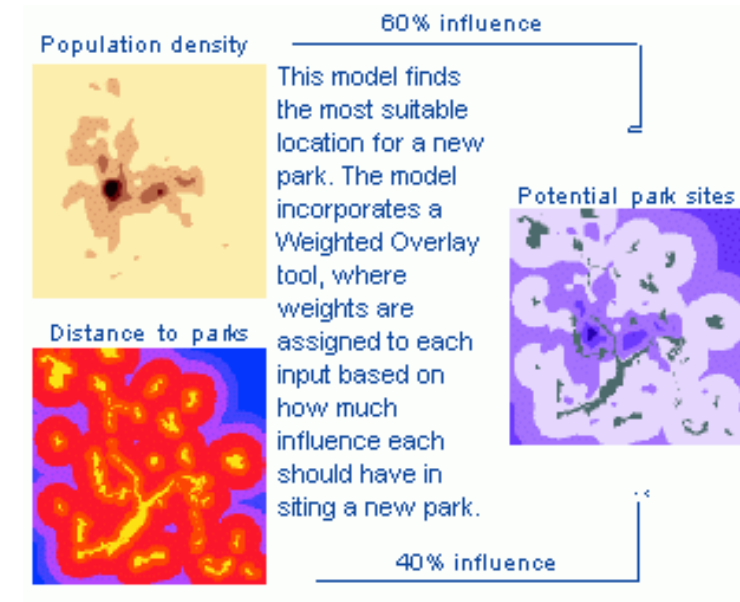

# Geoprocessing

It can be done:

- 1) Interactively (through Arc toolbox)
- 2) Using a model builder (ex. Suitability Analysis) – clear to show the workflow of multiple geoprocessing.

- 3) Python – good for geoprocessing automation (batch analysis)

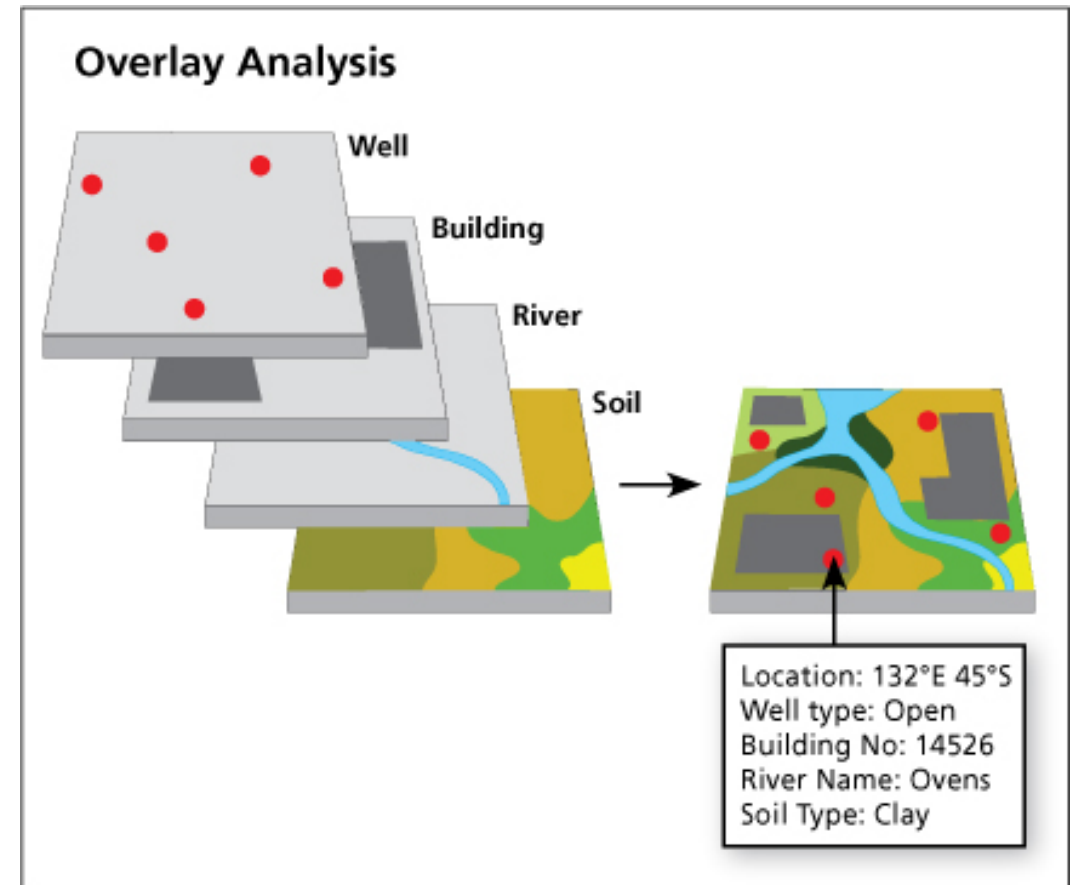

# Geoprocessing Operations We learn today

- Overlay toolset
  - clip
  - Union
  - Intersect
  - Spatial join
- Dissolve (spatial data reclassification)
- Merge
- Proximity toolset
  - Buffer

# Overlay analysis

Combining two layers to create a new output feature class containing *information from both of the inputs*.

- used for site selection and site suitability analysis
- Create new layer by combining features and attributes of two other layers
- Various methods - differ only in spatial extent of output
- Usually easier using raster data – more on this later

# Overlay analysis

One of the most basic questions asked of a GIS is: "What's on top of what?"

- *Point-in-polygon*: What is the total employment of large employers (points) in Ithaca (polygon)? How many bus stops (points) are there within our study area (polygon)? - "Within" is just another way of saying "on top of."
- *Line-in-polygon*: How many miles of bus routes (line) are within Tompkins County (polygon)?
- *Polygon-in-polygon*: Retrieve data for the census block groups (polygons) within the Central Business District (polygon).

# Polygon-in-polygon

Here the overlay of two polygons produces nine distinct polygons.

- One has the properties of both polygons,
- four have the properties of the yellow shaded polygon but not the blue (bounded) polygon.
- four are outside the yellow polygon but inside the blue polygon.

# Overlay: Clip

Extracts input features that overlay the clip features. Use this tool to cut out a piece of one dataset using one or more of the features in another dataset as a **cookie cutter**.

Spatial extent of 'clip' layer, attributes of original input layer

- **Not combining attributes of inputs**
- Input features retain their attributes.
- The attributes of boundary ("clip") layers are ignored.

# Overlay: Intersect

Computes a geometric intersection of the input features. Features or portions of features that overlap in all layers or feature classes will be written to the output feature class.

**Contains attributes of both input layers, spatial extent only where they intersect**

**Boolean Operation**

**Equivalent GIS function(s)**

INTERSECTION

# Environmental Analysis

## Input:

Roads, vegetative cover

=

**Output:** Intersection of roads and vegetative cover, attributes of both

Intersect: Contains attributes of both input layers, but the spatial extent only where the input layers intersect

FID	Shape*	LOCALID	RD_TYPE
6	Polyline	222192	1500
7	Polyline	220893	1500

+

FID	Shape*	VEG_TYPE
6	Polygon	CL
7	Polygon	SO
8	Polygon	SS

FID	Shape*	LOCALID	RD_TYPE	VEG_TYPE
6	Polyline	219378	1500	FC
7	Polyline	219384	1500	FC
8	Polyline	219380	1500	FC
9	Polyline	219380	1500	SO
10	Polyline	224631	1500	FC

Intersect: logging roads (lines) and vegetation types (polygons) are overlaid to create a new line layer

# Overlay: union

Contains attributes of both input layers, spatial extent of both input layers

**Boolean Operation**

**Equivalent GIS function(s)**

UNION

# Overlay: spatial join

- Joins attributes from one feature to another based on the spatial relationship.
- A spatial join matches rows from the **Join Features** values to the **Target Features** values based on their relative spatial locations.
- A new layer (output) is created
- **Target Layer:** The layer containing the features you want to enrich with additional attribute data
- **Join Layer:** The layer providing additional attribute data for the join.

Target Feature

Join Feature

Shape	TRI_ID	ZIP_Code
Point	1	10461
Point	2	10457
Point	3	10474
Point	4	10461
Point	5	10451
Point	6	10460
Point	7	10454

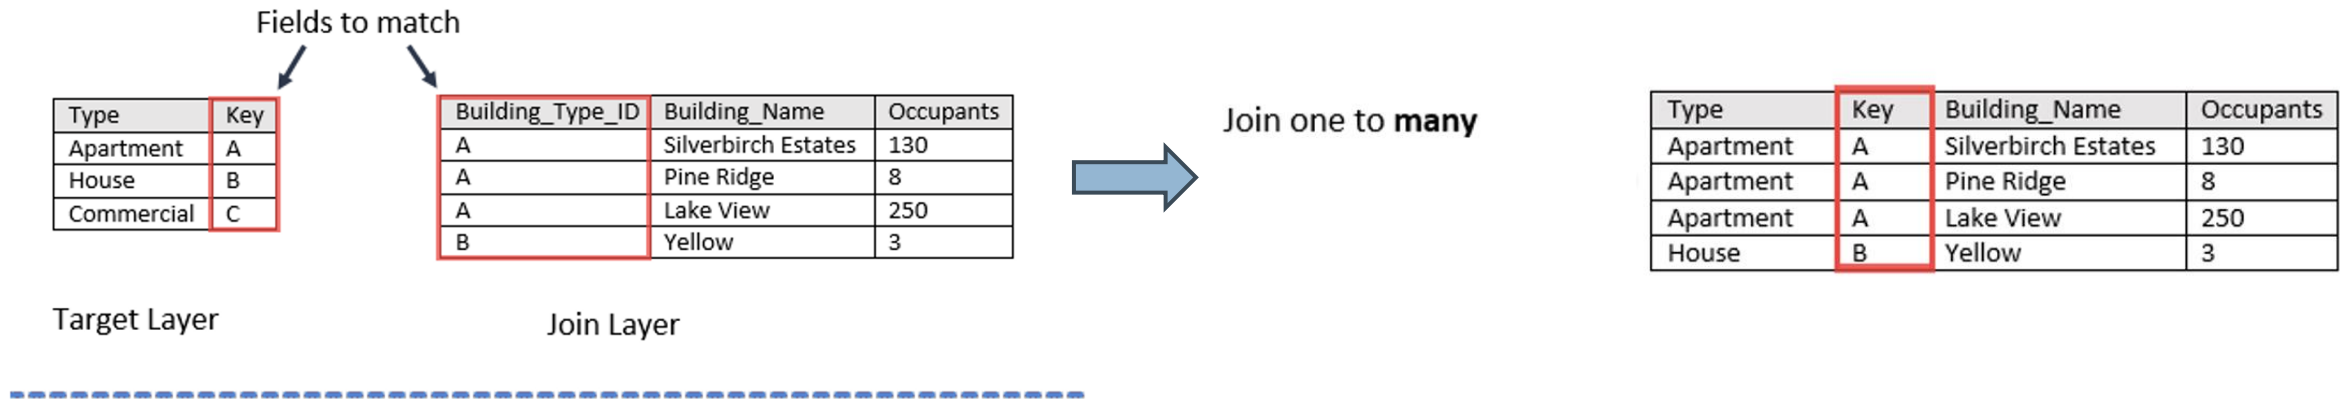

# Overlay: spatial join

- Spatial Join Relation: **One to One** and One to Many
- **One-to-one operation:** If multiple **join features** are found that have the same spatial relationship with a single **target feature**, the attributes from the multiple join features will be aggregated using a field map merge rule (e.g., count, mean, first/last, sum, etc).

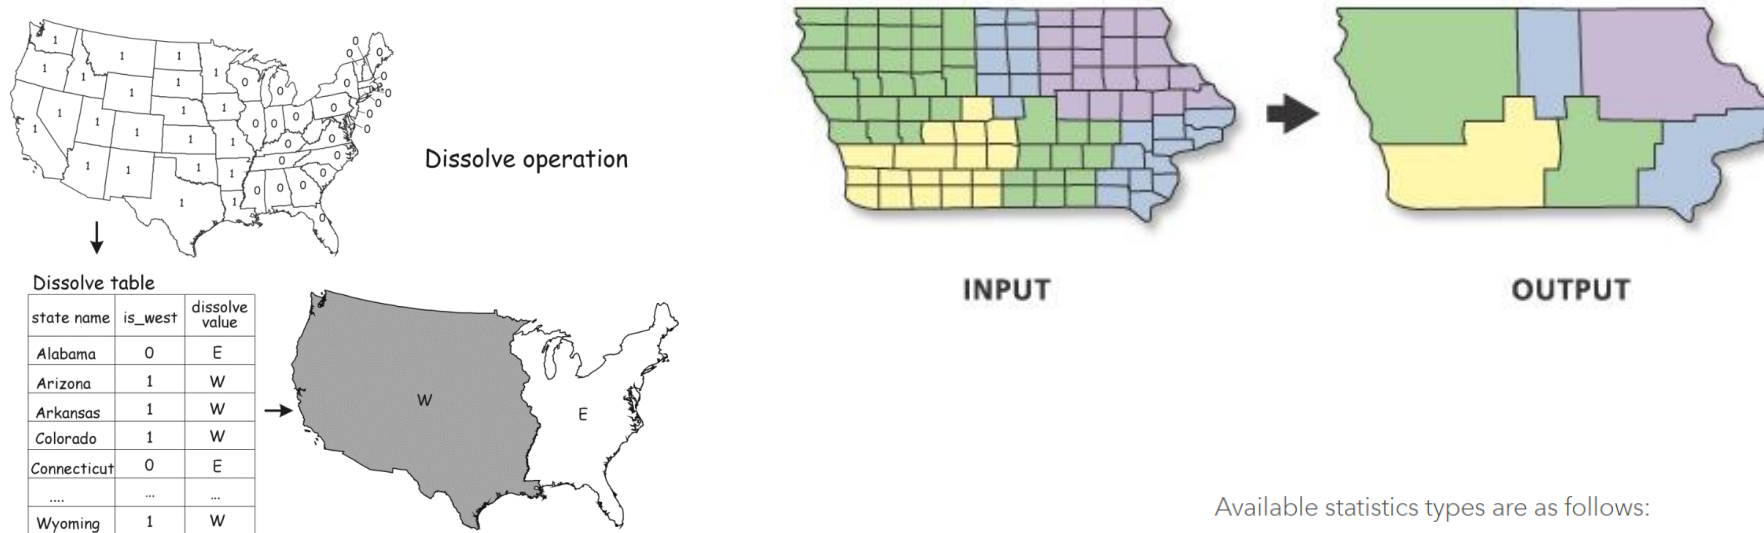

# Overlay: spatial join

- Spatial Join Relation: One to One and **One to Many**
- One-to-many operation: If multiple **join features** are found that have the same spatial relationship with a single **target feature**, the output feature class will contain multiple copies (records) of the target feature.

# Dissolve

- Group features together based on attributes

- The attribute table of the dissolved feature class
  - The field on which dissolve is based.
  - Additional fields to summarize information in the original features

Statistics Fields

Field	Statistic Type
AREA	Sum

Available statistics types are as follows:

- Sum**—The values for the specified field will be added together.
- Mean**—The average for the specified field will be calculated.
- Minimum**—The smallest value for all records of the specified field will be identified.
- Maximum**—The largest value for all records of the specified field will be identified.
- Range**—The range of values (maximum minus minimum) for the specified field will be calculated.
- Standard deviation**—The standard deviation of values for the specified field will be calculated.

# Dissolve – inside the attribute table

Input Feature

Dissolved Feature

# Dissolve

Specifies whether multipart features will be allowed in the output feature class.

- Checked—Multipart features will be allowed in the output feature class. This is the default.
- Unchecked—Multipart features will not be allowed in the output feature class. Individual features will be created for each part.

# Merge

Merge is used when you have two or more geographically **adjacent** layers, each containing the same type of features, and you want one layer that contains all their features.

# Proximity Analysis: Buffers

Buffering generates new polygons around existing points, lines, or polygons

- Identify all children within a 1 mile radius of a school (buffer around a point).
- Identify all large employers (points) within a 1/4 mile distance of a bus route (buffer around a line).
- Identify protected zones within 500 meters around a lake (buffer around lines)

**POINT**

**LINE**

**POLYGON**

# Proximity Analysis: Buffers

Creates buffer polygons around input features to a specified distance.
